## STUDIES RELATED TO WILDERNESS

### Bureau of Land Management Wilderness Study Areas

The Federal Land Policy and Management Act (Public Law 94-579, October 21, 1976) requires the U.S. Geological Survey and the U.S. Bureau of Mines to conduct mineral surveys on certain areas to determine their mineral resource potential. Results must be made available to the public and be submitted to the President and the Congress. This report presents the results of a geochemical survey of the Warm Springs Wilderness Study Area (AZ-020-028/029), Mohave County, Arizona.

### INTRODUCTION

In February and April of 1987, the U.S. Geological Survey conducted a reconnaissance geochemical survey of the Warm Springs Wilderness Study Area, Mohave County, Arizona.

The Warm Springs Wilderness Study Area (WSA) comprises about 150.5 mi<sup>2</sup> (389.7 km<sup>2</sup>, 96,000 acres) in the southern part of the Black Mountains in southwestern Mohave County, Arizona. The Warm Springs WSA is 15 mi southwest of Kingman, one mile southeast of Oatman, and one mile west of Yucca, Arizona (fig. 1). A paved road extending from Interstate Highway 40 to Oatman provides access to the northern and northwestern parts of the WSA. Unimproved roads accessible from Oatman and Yucca provide access to the rest of the area. Topographic features include dissected mesas with steep sides. Elevations range from 4,360 ft near Oatman to 1,000 ft near the southern boundary.

The WSA is underlain by Precambrian granite, gneiss, and schist that host pegmatite dikes and quartz veins and crop out in the northeastern part of the area. Throughout the rest of the WSA, the Precambrian rocks are extensively overlain by thick mid-Tertiary and Quaternary volcanic sequences (Great Basin GEM joint venture, 1983).

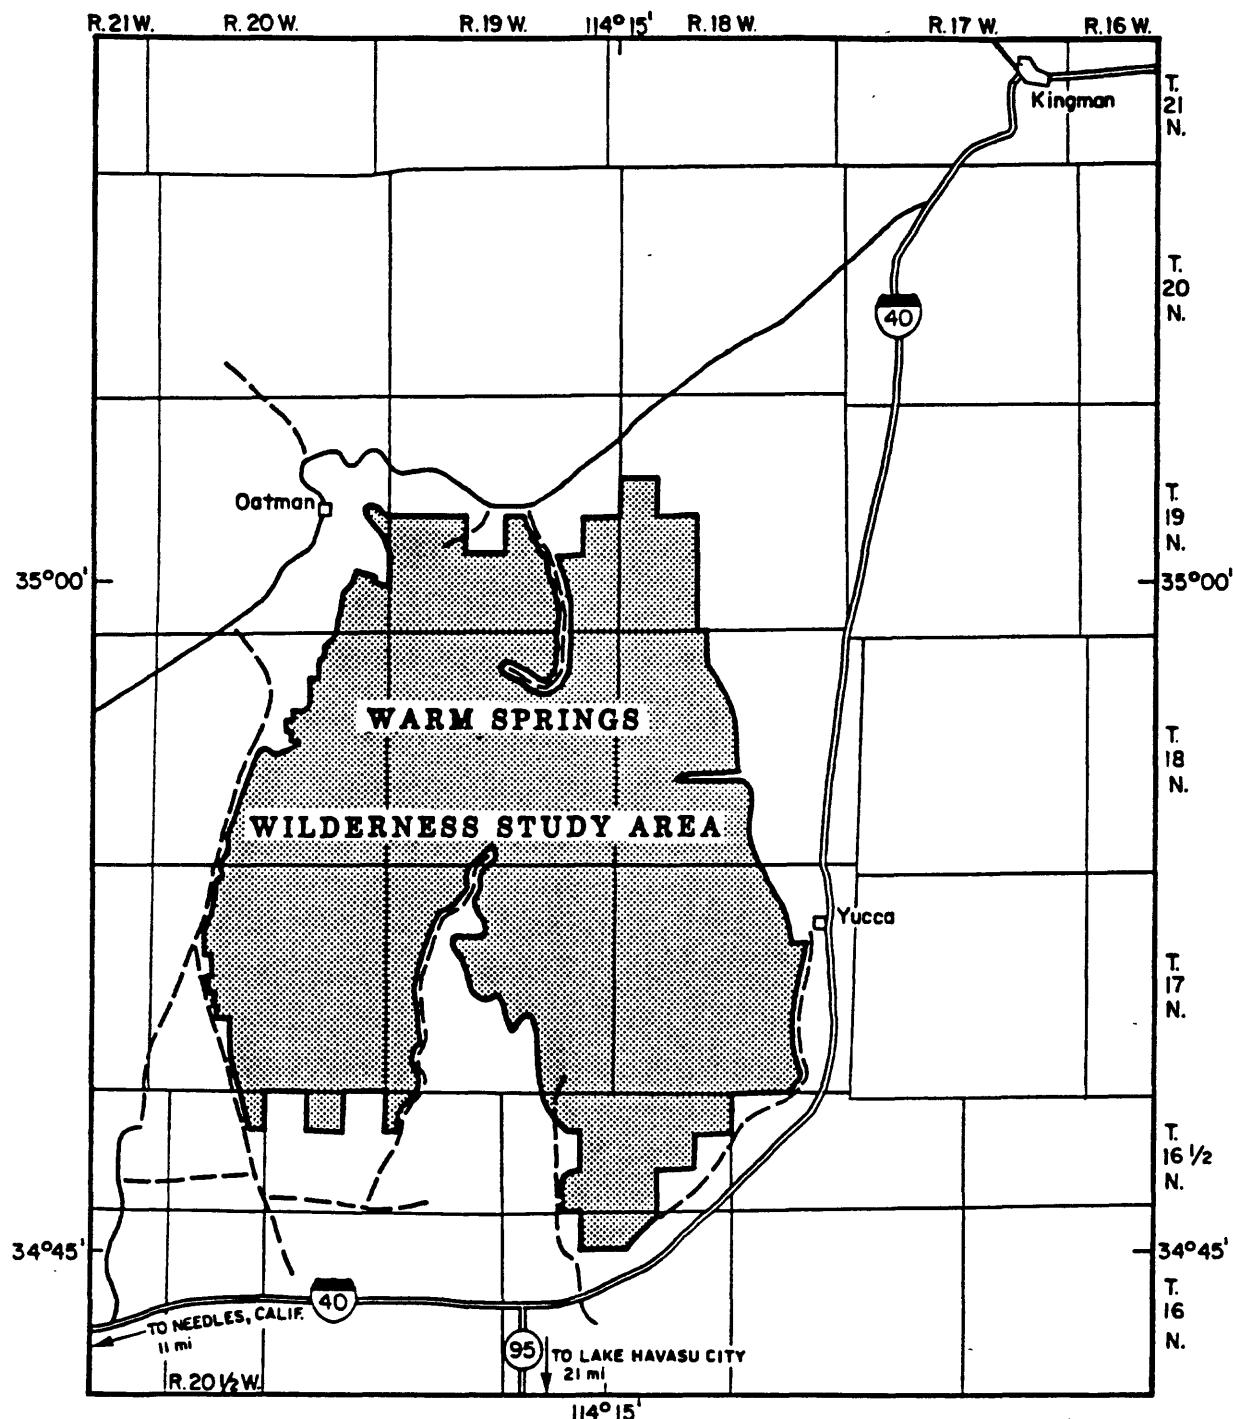

In the northwestern corner of the WSA, the Miocene volcanic formations are the Oatman Latite, Gold Road Latite, and an unnamed olivine basalt (Durning and Buchanan, 1984). These formations are exposed along a steep escarpment of Black Mesa adjacent to the Oatman district. Olivine basalt caps the mesas throughout the study area.

### METHODS OF STUDY

#### Sample Media

Analyses of the stream-sediment samples represent the chemistry of the rock material eroded from the drainage basin upstream from each sample site. Such information is useful in identifying those basins which contain concentrations of elements that may be related to mineral deposits. Heavy-mineral-concentrate samples provide information about the chemistry of certain minerals in rock material eroded from the drainage basin upstream from each sample site. The selective concentration of minerals, many of which may be ore related, permits determination of some elements that are not easily detected in stream-sediment samples.

Analyses of unaltered or unmineralized rock samples provide background geochemical data for individual rock units. On the other hand, analyses of altered or mineralized rocks, where present, may provide useful geochemical information about the major and trace-element assemblages associated with a mineralizing system.

## Sample Collection

Heavy-mineral-concentrate and stream-sediment samples were collected at 151 sites (plate 1). Rock samples were collected at 70 sites. Sampling density was about one sample site per 1.0 mi<sup>2</sup> for the stream sediments and heavy-mineral concentrates. The area of the drainage basins sampled ranged from 0.2 mi<sup>2</sup> to 2.0 mi<sup>2</sup>.

### Stream-sediment samples

The stream-sediment samples consisted of active alluvium collected primarily from first-order (unbranched) and second-order (below the junction of two first-order) streams as shown on USGS topographic maps (scale = 1:24,000). Each sample was composited from several localities within an area that may extend as much as 50 ft from the site plotted on the map.

### Heavy-mineral-concentrate samples

Heavy-mineral-concentrate samples were collected from the same active alluvium as the stream-sediment samples. Each bulk sample was screened with a 2.0-mm (10-mesh) screen to remove the coarse material. The less than 2.0-mm fraction was panned until most of the quartz, feldspar, organic material, and clay-sized material were removed.

### Rock samples

Rock samples were collected from various types of occurrences in the vicinity of the plotted site location. Descriptions of rock samples are in table 6.

## Sample Preparation

The stream-sediment samples were air dried, then sieved using 80-mesh (0.17-mm) stainless-steel sieves. The portion of the sediment passing through the sieve was saved for analysis.

Samples that had been panned in the field were air dried and sieved to -35 mesh; bromoform (specific gravity 2.85) was used to remove the remaining quartz and feldspar. The resultant heavy-mineral sample was separated into three fractions using a large electromagnet by placing the sample in contact with the face of the magnet (in this case a modified Frantz Isodynamic Separator). The most magnetic material (removed at a setting of 0.25 ampere), primarily magnetite, was not analyzed. The second fraction (removed at a setting of 1.75 ampere), largely ferromagnesian silicates and iron oxides, was saved for archival storage. The third fraction (the nonmagnetic material which may include the nonmagnetic ore minerals, zircon, sphene, etc.) was split using a Jones splitter. One split was hand ground for spectrographic analysis; the other split was saved for mineralogic analysis. (These magnetic separates are the same separates that would be produced by using a Frantz Isodynamic Separator set at a slope of 15° and a tilt of 10° with a current of 0.2 ampere to remove the magnetite and ilmenite, and a current of 0.6 ampere to split the remainder of the sample into paramagnetic and nonmagnetic fractions.)

Rock samples were crushed and then pulverized to minus 0.15 mm with ceramic plates.

## Sample Analysis

### Spectrographic method

The stream-sediment, heavy-mineral-concentrate, and rock samples were analyzed for 31 elements using a semiquantitative, direct-current arc emission spectrographic method (Grimes and Marranzino, 1968). The elements analyzed and their lower limits of determination are listed in table 1. Spectrographic results were obtained by visual comparison of spectra derived from the sample against spectra obtained from standards made from pure oxides and carbonates. Standard concentrations are geometrically spaced over any given order of magnitude of concentration as follows: 100, 50, 20, 10, and so forth. Samples whose concentrations are estimated to fall between those values are assigned values of 70, 30, 15, and so forth. The precision of the analytical method is approximately plus or minus one reporting interval at the 83 percent confidence level and plus or minus two reporting intervals at the 96 percent confidence level (Motooka and Grimes, 1976). Values determined for the major elements, iron, magnesium, calcium, and titanium, are given in weight percent; all others are given in parts per million (micrograms/gram). Analytical data for samples from the Warm Springs Wilderness Study Area are listed in tables 3, 4, and 5.

### Chemical methods

Rock and stream-sediment samples were also analyzed by atomic absorption emission spectroscopy (AA). Samples were analyzed for arsenic (As), antimony (Sb), bismuth (Bi), cadmium (Cd), and zinc (Zn) using AA, for gold (Au) using flame AA, and for mercury (Hg) using cold vapor AA. Limits of determination and references are listed in table 2.

Analytical results using these methods for stream-sediment and rock samples are listed in tables 3 and 5, respectively.

### ROCK ANALYSIS STORAGE SYSTEM

Upon completion of all analytical work, the analytical results were entered into a computer-based file called Rock Analysis Storage System (RASS). This data base contains both descriptive geological information and analytical data. Any or all of this information may be retrieved and converted to a binary form (STATPAC) for computerized statistical analysis or publication (VanTrump and Miesch, 1977).

### DESCRIPTION OF DATA TABLES

Tables 3-5 list the results of analyses for the stream-sediment, heavy-mineral-concentrate, and rock samples, respectively. For the three tables, the data are arranged so that column 1 contains the USGS-assigned sample numbers. These numbers correspond to the numbers shown on the site location map (plate 1). (For table 5, the 87 was removed from the beginning of each sample number.) Columns in which the element headings show the letter "s" below the element symbol are emission spectrographic analyses; "aa" indicates atomic absorption analyses. A letter "N" in the tables indicates that a given element was looked for but not detected at the lower limit of determination shown for that element in tables 1 and 2. For emission spectrographic analyses and AA analyses of As, Sb, Bi, Cd, and Zn, a "less

"than" symbol (<) entered in the tables in front of the lower limit of determination indicates that an element was observed but was below the lowest reporting value. For AA analyses of Au and Hg, an "N" entered in the tables indicates that the element was below the lowest reporting value. If an element was observed but was above the highest reporting value, a "greater than" symbol (>) was entered in the tables in front of the upper limit of determination. If an element was not looked for in a sample, two dashes (--) are entered in tables 3-5 in place of an analytical value. Because of the formatting used in the computer program that produced tables 3-5, some of the elements listed in these tables (Fe, Mg, Ca, Ti, Ag, and Be) may carry one or more nonsignificant digits to the right of the significant digits. The analysts did not determine these elements to the accuracy suggested by the extra zeros.

#### ACKNOWLEDGMENTS

A number of our colleagues also participated in the collection, preparation, and analyses of these samples: collection, Janet Jones, Sigurd Jaunaraajs, and Tracey Delaney; preparation, Ted Sparks and John Unruh; and analyses, Bryan Anderson and Olga Erlich.

87WS086R	silicified volcanic
87WS094R	andesite
87WS096R1	quartzite
87WS096R2	quartz vein
87WS098R	welded tuff
87WS099R1	volcanic
87WS099R2	volcanic
87WS100R	tuff
87WS106R	basalt
87WS109R1	andesite
87WS109R2	andesite
87WS111R1	metamorphosed granite
87WS111R2	silicified andesite
87WS121R	ash tuff
87WS123R1	gouge material
87WS123R2	gouge material
87WS123R3	granite
87WS124R1	schist
87WS131R	chloritized latite

**Table 6.--continued**

87WS132R	tuff
87WS136R	tuff
87WS142R	latite with quartz veins
87WS143R	oxidized latite
87WS144R1	volcanic
87WS144R2	volcanic
87WS147R	altered latite
87WS151R1	granite
87WS151R2	quartz monzonite
87WS152R	latite
87WS160R1	quartz vein
87WS160R2	intermediate volcanic
87WS161R1	clay gouge
87WS161R2	breccia
87WS161R3	intermediate volcanic
87WS161R4	quartz vein
87WS162R	ash tuff
87WS163R1	andesite
87WS163R2	iron stained andesite
87WS163R3	quartz vein
87WS164R	andesite
87WS165R	volcanic
